Social media sentiment can be measured, not guessed

How TASK-3 transformed 1,000 noisy posts into a visual map of brand and gaming sentiment.

Made with GAMMA

The project turned raw chatter into a decision-ready signal

Challenge

Social feeds mix praise, complaints, news, and irrelevant mentions.

Action

Audit, clean, aggregate, filter, rank, and visualize the conversation.

Outcome

Reveal where sentiment is balanced, favorable, negative, or polarized.

Made with GAMMA

The dataset was clean enough to trust

The analysis starts from a complete, duplicate-free 1,000-row dataset.

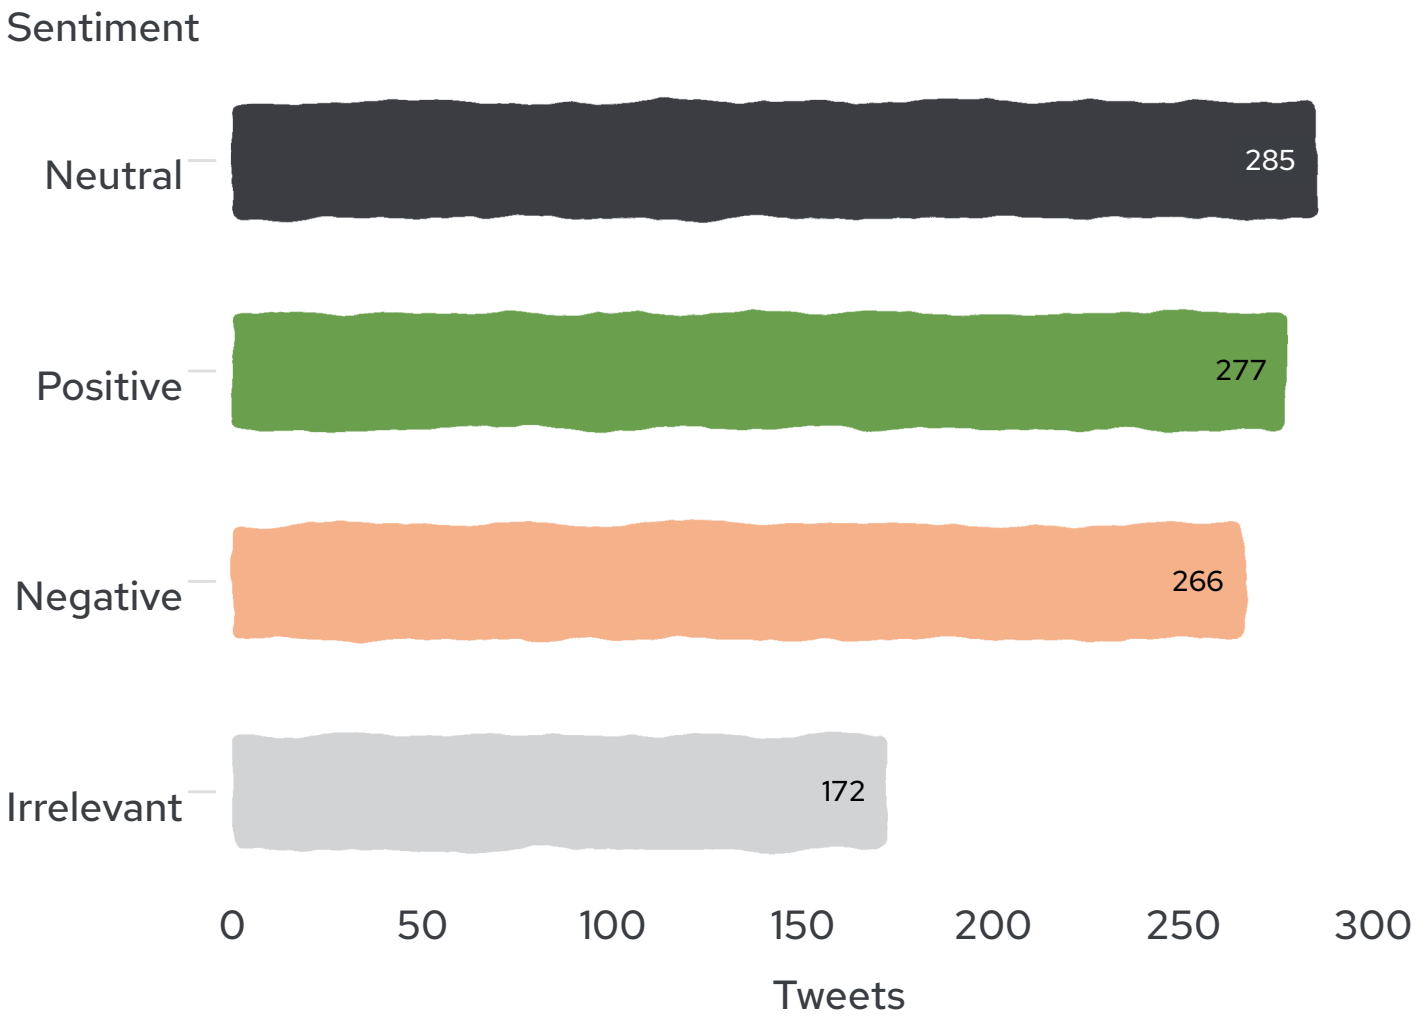

Scope: 1,000 tweets across 4 attributes: Id, Topic, Sentiment, and Text.

Coverage: technology brands, consumer brands, and gaming franchises.

Stack: Pandas, NumPy, Matplotlib, Seaborn, and WordCloud.

Made with GAMMA

Overall sentiment was almost evenly split

Neutral: 285 tweets, 28.5%.

Positive: 277 tweets, 27.7%.

Negative: 266 tweets, 26.6%.

Irrelevant: 172 tweets, 17.2%.

Made with GAMMA

Microsoft outperformed the dataset average on positivity

50.0% POSITIVE

Favorable conversation outweighed criticism by 2 to 1.

28 mentions analyzed: 14 positive, 7 negative, 6 neutral, 1 irrelevant.

Nearly double the 27.7% dataset-wide positive share.

Made with GAMMA

High-volume topics were also the most polarized

Topic-level aggregation exposed a pattern hidden by the macro average.

Grouped topic counts

Compare all topics across sentiment classes.

Top 5 negative topics

Locate concentrated criticism.

Top 5 positive topics

Locate concentrated praise.

Many heavily discussed brands and franchises attracted both strong praise and sharp criticism. Volume alone is not enough; sentiment segmentation is essential for interpretation.

Made with GAMMA

The analysis pipeline made the story repeatable

1. Inspect shape, schema, descriptive statistics, nulls, duplicates, and unique sentiment labels.
2. Count sentiment and topic frequencies to establish the macro picture.
3. Filter Microsoft with case-insensitive string matching.
4. Aggregate Topic × Sentiment counts with groupby().
5. Rank the most-discussed positive and negative topics with nlargest().

Made with GAMMA

The final outcome: a reusable framework for brand perception

Trust

Validated inputs before interpreting the conversation.

Clarity

Translated 1,000 posts into five visual analytical views.

Finding

Microsoft showed a strong positive signal, while high-volume topics revealed polarization.

Next step

Extend the dashboard with time trends, topic-level sentiment rates, and deeper text themes.
